

Supply Chain Analytics Report

A supply chain refers to the complete network of activities, people, organizations, and resources involved in producing and delivering a product from suppliers to end customers. It starts with sourcing raw materials or products from sellers, continues through order processing, transportation, and inventory handling, and ends with final delivery to customers. An effective supply chain ensures that the right product reaches the right customer at the right time and cost, while maintaining quality and profitability.

Dashboards are created for supply chain data to monitor performance, identify bottlenecks, and support data-driven decision-making. Instead of analyzing raw data manually, dashboards provide real-time and interactive visual insights into key areas such as sales trends, order fulfillment, inventory movement, customer demand, and seller performance. Supply chain dashboards help businesses track KPIs like total revenue, order volume, delivery status, and profit margins, while also enabling drill-through analysis to investigate issues at regional, product, or seller levels. This improves operational efficiency, reduces delays and costs, and enhances customer satisfaction.

The supply chain dataset typically contains transactional, product, customer, seller, location, and time-based data. Key data elements include order details (order ID, order date, order status, quantity), financial metrics (revenue, cost, profit, profit percentage), product information (product ID, product description, category), customer information (customer ID, customer state, region), and seller information (seller ID, seller state). Location data supports geographic analysis, while date fields enable monthly, yearly, and trend-based analysis. Together, this data structure allows the creation of interactive dashboards with slicers, tooltips, and drill-through features to analyze supply chain performance from multiple business perspectives.

Text Columns	Numerical Columns	Date Column
Location Seller name Transportation Mode Product type Order ID Stock Unit ID Route Shipping Carrier Inspection Results	Availability Price Detect Rating Lead time Manufacturing price Number of products sold Order Quantity Production Volume Shipping Cost Shipping Time Stock levels	Order date

The Index functions as the main navigation hub of the dashboard, allowing users to move easily between different report pages such as Monthly Analysis, Yearly Profit, Location Analysis, Drill-Through views, and KPI summaries. It provides a structured layout of buttons or tabs, each representing a specific analytical page. This helps users understand the overall report flow and quickly access the required insights without scrolling through multiple pages. In complex supply chain dashboards, the index improves usability by organizing information logically and making the report user-friendly.

From a business analysis perspective, the index ensures efficient exploration of data and better decision-making. Users can seamlessly switch between high-level summaries and detailed analytical views, which supports faster comparisons and deeper investigations. By reducing navigation effort, the index allows analysts and managers to focus more on interpreting insights rather than searching for information, improving productivity and analytical efficiency.

The slicers represent interactive filtering tools that allow users to control the data displayed in charts and visuals. Slicers typically include fields such as date, state, product, seller, or order status, and when a selection is made, all connected visuals update instantly. This enables users to focus on specific segments of the supply chain instead of viewing aggregated data, making analysis more precise and relevant.

The impact of slicers on charts is highly significant in business analysis. They allow users to compare scenarios, identify trends within selected filters, and uncover insights that may be hidden in overall data. Slicers transform static charts into dynamic visuals, support what-if

analysis, and empower users to independently explore supply chain performance, leading to more accurate insights and data-driven decisions.

The Product Analysis image is designed to evaluate and compare product performance across key business metrics such as total revenue, number of orders, profit, and profit percentage. It is usually displayed using bar charts, column charts, or tables where each product or product category is represented visually, making it easy to identify top-performing and underperforming products. The image responds dynamically to slicers like date, state, seller, or order status, ensuring that the analysis always reflects the selected business context. This allows users to understand how different products contribute to overall supply chain and sales performance.

From a business analysis perspective, the Product Analysis image helps organizations make product-level decisions such as optimizing inventory, improving pricing strategies, and planning promotions. By clearly showing which products generate high revenue but low profit—or vice versa—business users can identify cost issues, demand patterns, and growth opportunities. It also supports strategic planning by highlighting product trends and performance consistency over time.

The tooltip in the Product Analysis image provides additional, detailed information when users hover over a specific product or data point. Instead of overcrowding the main visual, the tooltip displays key metrics such as exact revenue value, order count, profit margin, and comparisons with previous periods. This contextual information allows users to quickly understand the reasons behind a product's performance without navigating away from the chart.

When users drill through from the Product Analysis image, the Monthly Analysis image displays month-wise performance for the selected product. Instead of showing overall sales, the drill-through applies the product filter automatically and breaks down revenue, orders, or profit by month. This helps identify seasonality, demand fluctuations, and short-term performance changes for that specific product. From a business analysis perspective, this view supports inventory planning, promotional timing, and demand forecasting by showing when a product performs strongly or weakly during the year.

The Yearly Profit image focuses on evaluating the long-term profitability of a selected product across different years. Through drill-through, the product context is preserved, allowing users to compare profit trends year over year. This helps determine whether a product’s profitability is improving, stable, or declining over time. From a business perspective, this image supports strategic decision-making such as pricing revisions, cost optimization, and investment planning by highlighting sustainable profit trends rather than short-term sales spikes.

The Monthly Moving Average image is used to smooth out short-term volatility in monthly product performance by applying a moving average calculation. When drilled through from Product Analysis, it displays a trend line that reduces the impact of sudden peaks or drops in sales or profit. This makes it easier to identify the true performance direction of a product. In business analysis, this image is valuable for accurate forecasting, trend identification, and avoiding reactive decisions based on temporary fluctuations, especially in volatile markets.

The Aging Analysis image, accessed through drill-through from the Product Analysis view, shows outstanding balances or pending orders related specifically to the selected product, categorized into aging buckets such as 0–30 days, 31–60 days, and overdue periods. This analysis helps businesses understand payment delays, credit risk, and cash flow impact associated with a product. From a business analysis standpoint, it supports better receivables

management, risk mitigation, and policy adjustments by identifying products linked to higher overdue amounts or delayed payments.

The Shipping Distribution image is used to analyze how orders are distributed across different shipping modes, delivery timelines, or shipment statuses within the supply chain. This image is typically shown using visuals such as bar charts, column charts, or pie/donut charts, where each segment represents a shipping category like standard, expedited, or delayed shipments. The visual responds to slicers and drill-through filters applied in the report—such as product, state, seller, or time period—ensuring that shipping performance is analyzed in the correct business context. This helps users quickly understand which shipping methods are most commonly used and where delays or inefficiencies may exist.

The tooltip in the Shipping Distribution image provides detailed, contextual insights when users hover over a specific shipping category. It usually displays additional metrics such as number of orders shipped, shipping cost, average delivery time, or percentage contribution. This allows analysts to assess the operational impact of each shipping method without overcrowding the main chart. From a business analysis perspective, this image and its tooltip support logistics optimization, cost control, and service-level improvement by highlighting delivery performance issues, enabling comparisons across shipping methods, and supporting data-driven decisions to improve overall supply chain efficiency and customer satisfaction.

Month Name	Location	Total Revenue	Total Orders
Jan	California	85,27,391.70	60
Jan	Florida	1,30,79,526.25	80
Jan	Illinois	1,33,10,217.59	73
Jan	New York	1,20,63,475.98	78
Jan	Texas	1,19,57,622.67	63
Jan	Washington	1,00,14,960.26	62
Feb	California	1,28,19,486.70	67
Feb	Florida	1,14,33,933.16	65
Feb	Illinois	1,29,51,731.26	81
Feb	New York	1,08,01,744.57	63
Feb	Texas	1,11,20,276.96	62
Feb	Washington	1,15,25,149.50	67
Mar	California	1,26,91,390.07	75
Mar	Florida	1,06,88,421.36	66
Mar	Illinois	1,04,10,394.74	60
Mar	New York	1,24,42,984.24	73
Mar	Texas	1,09,82,839.42	61
Mar	Washington	1,33,47,190.47	64
Apr	California	1,53,23,944.74	86
Apr	Florida	1,36,27,373.80	72
Total		84,85,84,291.50	3805

Total Revenue and Total Orders by Month Name and Location

The Location image provides a geographic view of supply chain and sales performance by visualizing data across different states or regions. It is typically displayed using a map visual where each location is highlighted based on key measures such as total revenue, order volume, or profit. The use of color intensity or markers helps users quickly identify high-performing and low-performing regions at a glance. This image responds dynamically to slicers like date, product, seller, or order status, ensuring that the geographic insights always reflect the selected business context. As a result, users can easily compare regional performance and detect geographic patterns or disparities.

The drill-through functionality from the Location image allows users to move from a high-level regional overview into detailed, location-specific analysis. By right-clicking on a selected state or region and choosing a drill-through option, the report carries the selected location as a filter to other report pages such as Customer State, Seller State, or detailed sales views. This enables users to investigate the underlying reasons behind a region's performance, such as customer demand, seller contribution, or operational issues. The drill-through ensures consistency and accuracy by maintaining the context of the selected location across all detailed visuals.

From a business analysis perspective, the Location image combined with drill-through supports region-based decision-making. It helps businesses identify strong and weak markets, optimize regional sales strategies, plan logistics and inventory distribution, and prioritize expansion or improvement efforts. By transforming geographic data into interactive insights, this approach enables analysts and managers to connect *where* performance happens with *why* it happens, leading to more informed and actionable supply chain and sales decisions.

The Defective Rating image is used to analyze product quality by showing the proportion or level of defective items across products, categories, sellers, or locations. This visual is commonly displayed using bar charts, column charts, or rating-based visuals, where higher values indicate higher defect rates. It responds to slicers such as product, seller, state, or time period, ensuring that defect analysis is context-specific. By visualizing defect levels clearly, the image helps users quickly identify products or suppliers associated with quality issues.

The tooltip in the Defective Rating image provides deeper insights when users hover over a data point. It typically shows supporting details such as total units sold, number of defective units, defect percentage, and sometimes comparisons with previous periods. This allows analysts to understand whether a high defect rate is based on large volumes or isolated cases. From a business analysis perspective, this image helps improve quality control, supplier

evaluation, and risk management by identifying problem areas early and supporting corrective actions to reduce returns, customer dissatisfaction, and operational losses.

The Location by Total Revenue and Orders image presents a geographic performance comparison by showing how different states or regions contribute to overall revenue and order volume. This image is often displayed using a map or combined bar/column visual, where locations are compared based on two key measures—revenue and orders. The visual dynamically responds to slicers such as date, product, seller, or order status, allowing users to analyze regional performance under different business conditions. This makes it easy to spot high-revenue regions, high-demand areas, or locations with strong order volume but lower revenue.

The tooltip in this image adds valuable context by displaying detailed metrics when users hover over a specific location. It typically shows exact revenue values, total orders, average order value, and sometimes profit or growth indicators. This allows analysts to quickly interpret regional performance without overcrowding the main visual. From a business analysis standpoint, this image supports regional strategy planning, resource allocation, logistics optimization, and market expansion decisions by clearly showing *where* revenue and demand are strongest and how they compare across locations.

The Order Status image is designed to provide a clear overview of how orders move through different stages of the supply chain, such as *Completed*, *Pending*, *Shipped*, *Cancelled*, or *Returned*. This image is typically displayed using bar charts, column charts, or donut charts, where each segment represents an order status. The visual responds dynamically to slicers like date, product, seller, or location, ensuring that the order flow analysis is always aligned with the selected business context. This helps users quickly understand the current operational state of orders.

From a functional perspective, this image uses aggregated measures such as total order count or percentage distribution by status to highlight operational efficiency. For example, a high number of pending or cancelled orders may indicate issues in inventory availability, logistics delays, or customer dissatisfaction. By presenting this information visually, the image makes it easier to detect bottlenecks and inefficiencies that may not be obvious in raw data tables.

The tooltip in the Order Status image adds an additional layer of insight when users hover over a specific status. It typically shows detailed metrics such as total orders under that status, associated revenue value, average delivery time, or comparison with previous periods. This contextual information allows analysts to assess the financial and operational impact of each order status without cluttering the main visual.

From a business analysis standpoint, the Order Status image helps improve order fulfillment performance, customer satisfaction, and operational control. It supports data-driven decisions such as prioritizing delayed orders, improving logistics processes, and reducing cancellations or returns. Overall, this image plays a key role in monitoring supply chain health and ensuring smooth order execution.

The Top 5 Sellers image highlights the highest-performing sellers based on key metrics such as total revenue, order volume, or profit. This image is usually shown using a bar or column chart where sellers are ranked from highest to lowest, making performance comparison simple and intuitive. The visual dynamically responds to slicers like time period, product category, state, or order status, ensuring that the top sellers displayed reflect the current analytical focus.

This image relies on ranking functions and measures to dynamically calculate and display only the top five sellers under the selected filters. By limiting the view to the top performers, the image reduces visual complexity while drawing attention to sellers who contribute most significantly to business performance. This makes it easier for stakeholders to focus on key contributors rather than scanning through long lists of sellers.

The tooltip in the Top 5 Sellers image provides deeper insights when users hover over a seller bar. It typically shows detailed metrics such as total revenue, number of orders, profit margin, and sometimes previous-period comparisons. This helps analysts understand not just *who* the top sellers are, but *why* they rank highly—whether due to high sales volume, strong margins, or consistent performance.

From a business analysis perspective, the Top 5 Sellers image supports vendor management, performance benchmarking, and strategic partnerships. It helps businesses identify reliable sellers, allocate resources effectively, negotiate better terms, and plan regional or category-based expansion. By combining ranking logic, slicer interaction, and informative tooltips, this image turns seller performance data into actionable insights.

The Total Revenue and Total Orders KPI image provides a high-level snapshot of overall business performance and is usually displayed using KPI cards or tiles. These cards prominently show the total revenue generated and the total number of orders within the selected time period. The values dynamically update based on slicer selections such as date, product, seller, state, or order status, ensuring that users are always viewing the most relevant

performance summary. This visual is often placed at the top of the report to immediately communicate business health.

From a functional perspective, this image uses aggregated measures that calculate total revenue and order count from transactional data. Because the KPIs are connected to slicers and filters, users can instantly see how revenue and order volume change across different scenarios. This allows analysts to compare performance across time periods, regions, or product segments without navigating to separate pages.

The KPI image is also effective in highlighting relationships between metrics. For example, a rise in total orders with flat revenue may indicate lower average order value, while increasing revenue with stable order counts may suggest improved pricing or higher-value products. These insights are critical for identifying demand patterns and revenue drivers.

From a business analysis perspective, Total Revenue and Total Orders KPIs support executive-level decision-making, performance tracking, and strategic planning. They help monitor growth, evaluate marketing effectiveness, forecast demand, and assess overall supply chain performance in a concise and easily interpretable format.

The Month-over-Month (MOM) and Year-over-Year (YOY) image is designed to measure growth and performance changes over time. This image is typically displayed using line charts, column charts, or KPI indicators that show percentage or value changes compared to the previous month or the same period in the previous year. It responds dynamically to slicers such as date, product, seller, or location, allowing users to analyze growth trends in different business contexts.

This image relies on time-intelligence functions and calculated measures to derive MOM and YOY values. By comparing current performance against historical periods, it highlights whether the business is improving, declining, or remaining stable. These calculations help normalize

seasonal effects and provide meaningful performance comparisons rather than relying on absolute values alone.

The tooltip in the MOM and YOY image often provides additional context by showing current period values, previous period values, and the calculated percentage change. This allows users to understand the drivers behind growth or decline without cluttering the visual. Analysts can quickly validate trends and identify periods with unusual performance changes.

From a business analysis standpoint, the MOM and YOY image is critical for trend analysis, forecasting, and performance benchmarking. It helps businesses evaluate growth consistency, measure the impact of strategic initiatives, identify early warning signs of decline, and support long-term planning. By using time-based comparisons, this image turns historical data into actionable insights that guide informed business decisions.
